### Re: Gateway East Bus Lane Proposal

Dear Acting Secretary Tesler,

Last week, the Brookline Transportation Board voted to conditionally approve a concept for the Gateway East Bus Lane, advancing the project to the Massachusetts Department of Transportation (MassDOT) for design and approval. MASCO and its members share the concern that, combined with ongoing reductions to MBTA service, this proposal will result in gridlock that threatens patient safety and makes our essential frontline work even harder to perform.

MASCO is a regional and national leader in multi-modal transportation solutions. Our member-driven transportation demand management programs, shuttle system, and investments in local walk and bike infrastructure continue to support modal shift towards more transit, walking, and biking. MASCO strongly supports transit, and we believe that dedicated bus lanes are an important tool in facilitating better bus travel. We agree with the goals that this proposal seeks to achieve and the importance of the three bus routes that use this corridor to transit-dependent populations, including frontline medical and service workers in the Longwood Medical and Academic Area (LMA).

However, as currently designed, this proposal will improve travel for only the 25% of road users who travel by bus, at the significant expense of the 75% of road users traveling by other modes, and significantly impacting access to the LMA. The LMA has unique travel needs inherent to the critical, life-saving work of our member institutions. It's estimated that over 95% of patients traveling by car to access specialty care have no other option due to compromised immunity, treatment discharge requirements, or disability. We believe this proposal should take the patient population into careful consideration due to the proximity to the LMA and expand its analysis beyond what is necessary for similar projects in the Greater Boston area.

We raise the following concerns for MassDOT's consideration:

#### 1. Reducing Route 9 eastbound to one lane will cause "extensive disruption."

The proposal the Transportation Board conditionally approved requires the reduction of Route 9, which is directly under MassDOT jurisdiction, from two lanes to one lane in the

eastbound direction from a point just east of Cypress Street to High Street. However, the Town of Brookline's traffic consultant, VHB, stated in the attached memo on page 14 that, while dedicated bus lanes can be installed in the westbound direction without extensive disruption, dedicated bus lanes in the eastbound direction will likely require more substantive design changes, such as potential reconstruction of the separated bike lane and further coordination with MassDOT to modify sections of state highway. The Town of Brookline proceeded with bus lanes in both directions despite this concern.

## **2. Delays will extend an already lengthy peak period by 30 minutes.**

Under pre-pandemic traffic conditions and assuming no diversions, this proposal will result in +292 seconds of vehicle/person or five minutes of delay, according to VHB's analysis for the Town. The peak period is already long, extending to 10 a.m., and the analysis states that this proposal would further extend the morning peak period by 30 minutes. Also, in the PM heading outbound, it is +225 seconds or almost 4 minutes. These delays are problematic for patients that must travel by car for health reasons and employees that are currently carpooling or that have no choice but to drive.

## **3. There are outstanding questions about emergency vehicle access.**

While we were relieved to hear the Transportation Board clarify that emergency vehicle would have access to the bus lanes, longer vehicles queues on Route 9 eastbound approaching the bus lanes will present delays for emergency vehicles. It was suggested at the Transportation Board meeting last week that emergency vehicles could pass regular traffic on Route 9. However, the impacted section of Route 9 has a median, not to mention a curbside parking lane that would make this extremely difficult, if not impossible. This unresolved issue is a risk to public safety, and we strongly encourage MassDOT to identify a plan for sufficient emergency vehicle access before a pilot is implemented.

## **4. The broad regional impacts have not been explored.**

While this proposal focuses on sections of roadway within the Town of Brookline, its impacts extend throughout the region. This proposal will regionally affect access for commuters traveling from the west, causing spillover impacts to the local neighborhood and trip diversion to already congested regional roadways such as Beacon Street and I-90. According to the Town of Brookline's analysis, a 30% diversion will be required to maintain pre-pandemic traffic levels. The local alternatives for traffic flows are Walnut Street, Beacon Street to Coolidge Corner, or regionally Storrow Drive/Copley to the Bowker Overpass. While some volume may shift to I-90, travelers from neighboring towns are more likely to shift over to Beacon Street, leading to more traffic in Coolidge Corner and Longwood Avenue. We hope that MassDOT will explore and consider these regional impacts, including implementing of a robust set of metrics.

## 5. The potential benefits are overstated.

The potential benefits to the only 25% of roadway users that ride the bus have not been sufficiently weighed against potential adverse impacts to all other roadway users, including delays for buses before reaching the bus lane if queues increase and that, while only two of the three bus routes will be able to use the bus lane, it will impact all vehicle traffic. These concerns are well-described in the attached letter by Town Meeting Member and resident John Doggett.

MASCO and its members also feel strongly that it is problematic to implement a pilot during pandemic conditions, especially for a proposal at the front door of one of the region's major medical, emergency, and trauma centers, and major employment hub.

Should the pilot proceed under any circumstance, MASCO supports the Town's commitment to define and analyze metrics to evaluate the pilot's benefits and impacts. We also agree that these metrics must be defined in advance of implementation, with pilot operations identified and expected benefits enumerated. We propose that, at a minimum, the following metrics be considered by MassDOT, the MBTA and Town of Brookline and that key stakeholders are included in determining what constitutes a success or failure of the pilot:

1. Impacts to emergency vehicle access on terms agreed to with local ambulance services and in discussion with MASCO and area hospitals;
2. Diversion impacts including to local roadways, I-90, and other regional roadways such as Storrow Drive during the peaks and shoulders;
3. Assessment of queue lengths, including modeled results of pre-COVID operations and field-verification of current queue lengths, including but not limited to:
  - a. On Route 9 especially approaching the High Street/Washington Street intersection in the AM peak hour;
  - b. On Brookline Avenue heading out of the LMA towards Washington Street, especially in the PM peak hour.
4. Bus travel times by route and by time period for each direction, using 50th and 90th percentile (pre-COVID and current);
5. Overall vehicle travel time on critical moves through Route 9 east from an intersection before the expected queues through to Brookline Avenue or Huntington Avenue; and,
6. Bus ridership both locally and on the entire route.

We would appreciate the opportunity to further engage on this proposal. We wish to work with MassDOT, the MBTA, and the Town of Brookline on a viable solution that improves bus access without jeopardizing patient, visitor, employee, or emergency vehicular access to the LMA.

Thank you for the opportunity to comment. Please contact me with any questions at 617-632-2776.

Sincerely,

Re: Gateway East – Transit Improvements  
Traffic Design Implications

---

## Introduction

In support of the potential to provide dedicated bus lanes along a key bus route corridor, VHB has reviewed three concepts developed by the MBTA that attempt to improve transit operations along the Route 9 corridor (known as Gateway East) in Brookline, Massachusetts. This memo details the methodology and analysis of the associated traffic review and provides suggestions for the MBTA and the Town's consideration. Physical implications to the ongoing construction project (MassDOT's Tip Project 605110) in the area are covered in a separate memorandum. The MBTA has identified this corridor as a critical transit area and has an opportunity to improve transit ridership by making lane configuration modifications. These modifications are illustrated in concepts provided by the MBTA and are included in the attachments.

The study area consists of three signalized intersections: Boylston Street/ Washington Street (Route 9) at Washington Street/ High Street; Washington Street (Route 9) at Pearl Street/ Walnut Street; and Washington Street (Route 9) at Brookline Avenue.

## Methodology

The analysis prepared for this evaluation focuses on impacts to traffic operations with and without the proposed dedicated transit lanes, as measured against the benefits/impacts to transit users within the system. With the goal to improve transit schedules/headways and encourage ridership, it was determined that person-trip comparisons along this busy transit corridor would be a preferred comparison to evaluating benefits versus impacts. This is accomplished by using the MassDOT Project 605110 Synchro model and MBTA ridership data for the Route 65 and 66 buses. With the synchro model as a baseline condition, each concept was compared to determine overall vehicle impacts.

## Ridership Data

MBTA ridership data was evaluated to understand the peak hour impacts to total persons along the corridor. The ridership data consisted of a composite day during 2019 of the number of buses and riders, which highlights peak hour buses and riders for both inbound and outbound routes. Use of the composite day allows the analysis to consider seasonal factors that may affect ridership or schedule adherence and also eliminates any impact COVID 19 is currently having on ridership. Table 1 shows the ridership statistics for the 65 and 66 Routes during the typical weekday peak hours at the study area.

**Table 1 Ridership Data**

Route	Direction	Weekday Morning Peak Hour		Weekday Evening Peak Hour	
		Buses	Riders	Buses	Riders
65	Inbound	6	322	3	30
	Outbound	3	19	5	223
66	Inbound	7	283	6	214
	Outbound	8	212	6	233

Table 1 shows that during a typical peak hour, there are 605 morning peak hour riders on 13 buses and 456 evening peak hour riders on 11 buses. Route 65 provides service up Washington Street to the west and Brookline Avenue to the east of the study area. Route 66 provides service up Harvard Street to the west and continues along Huntington Avenue to the east of the study area. While Route 60 does travel through the study area, the bus would not utilize the proposed dedicated bus lanes, so Route 60 ridership data was not analyzed. Route composite data is included in the Attachments to this memorandum. The MBTA has anecdotal data that suggest ridership on the Route 65 and 66 buses may increase by as much as five percent during peak hours if dedicated bus lanes were in place. This would increase ridership to 635 morning and 478 evening riders on the two services and potentially eliminate 20 to 30 vehicle that currently transport these riders. The MBTA also has anecdotal data that dedicated bus lanes decrease traffic volumes along the route by 10 to 20 percent. This is discussed further below (see reduced/diverted demand).

## Traffic Operations Analysis

The first step in understanding the benefits and impacts of the dedicated bus lane concepts is to assess the impacts to roadway capacity that would be realized for each option. Under each concept being evaluated, Route 9 eastbound would essentially be reduced to one through lane and Route 9 westbound would be reduced to two through lanes, with only a single turn lane to/from Washington Street and the Brookline Village area. Intersection capacity analyses were conducted with respect to full build traffic volume conditions expected once the MassDOT construction is complete. Capacity analyses provide an indication of how well the roadway facilities serve the traffic demands placed upon them. Roadway operating conditions are classified by calculated levels-of-service. The build traffic volumes do not take into account reduction in traffic due to the COVID-19 pandemic, however, it is estimated that traffic volumes in the area are currently about 40 percent lower than pre-pandemic conditions. The volumes also do not reflect a reduction in corridor traffic due to the provision of dedicated bus lanes. This is discussed further in the section below on reduced/diverted demand.

## Level of Service Criteria

Level-of-service (LOS) is the term used to denote the different operating conditions that occur on a given roadway segment under various traffic volume loads. It is a qualitative measure that considers a number of factors including roadway geometry, speed, travel delay, freedom to maneuver, and safety. Level-of-service provides an index to operational qualities of a roadway segment or an intersection. Level-of-service designations range from A to F, with LOS A representing the best operating conditions and LOS F representing the worst operating conditions.

For this study, capacity analyses were completed for the signalized intersections within the study area using Synchro traffic analysis software. The evaluation criteria used to analyze the signalized study area intersections is based on the *2010 Highway Capacity Manual (HCM)*<sup>1</sup>.

## Intersection Capacity Analysis

Table 2 summarizes the capacity analyses for the three signalized intersections under each concept. Operationally, Concepts 2 and 3 would provide the same traffic delays and levels of service. Therefore, these results are combined in the tables below. It is noted that moving the bus stop to the far side (Concept 3) will have some improved effect in traffic flow through the intersection, as there would be no need for vehicles to move around waiting buses. However, these effects cannot be reasonably modeled in Synchro. The capacity analyses worksheets are included in the Attachments to this memorandum.

In addition to the intersection capacity analysis summary tables, queue diagrams illustrating the 95<sup>th</sup>-percentile queue for each movement were developed for each intersection. Queue diagrams were developed for the weekday morning peak hour of operations at the intersections of Route 9 at Washington Street / High Street and Route 9 at Walnut Street / Pearl Street and for the weekday evening peak hour of operations at the intersection of Route 9 at Brookline Avenue, representing the peak hours with the largest queues at each intersection. The queue diagrams are included in the Attachments to this memorandum.

**BOLD** – Movement altered by bus lane.

- a Volume to capacity ratio.
- b Average total delay, in seconds per vehicle.
- c Level-of-service.
- d 50th percentile queue, in feet.
- e 95th percentile queue, in feet.
- ~ Volume exceeds capacity, queue is theoretically infinite.
- # 95th percentile volume exceeds capacity; queue may be longer.
- m Volume for 95th percentile queue is metered by upstream signal.

As shown in Table 2, all intersections experience a LOS F during the morning peak hour in the Build condition, while in the evening peak hour the Route 9 at Washington Street/ High Street intersection and the Route 9 at Walnut Street/ Pearl Street intersection experience a LOS E. The Gateway East project was developed to manage congestion and queuing through the traffic signal system. The operations along the corridor at all study area intersections degrade from the Build conditions with the dedicated bus lane in place. Specifically, the movements where bus lanes are incorporated in lieu of a vehicle travel lane experience the most impacts where many of the movements double their queues. This is reflective of the elimination of a through lane in each direction. Additionally, the level of service results reflects the need to reduce eastbound Route 9 (Boylston Street) outside of the project limits from two to one through lane. This is necessary to maintain traffic safety and allow traffic to merge to one lane prior to reaching the firehouse.

### Person-Delay

As mentioned previously, the concepts along this corridor were also analyzed using person-delay in lieu of vehicle-delay to properly assess the incentives of the implementation of bus-only lanes in the study area. Person delay was calculated for the total amount of time in seconds it takes an individual person to travel the corridor as well as for the cumulative delay in hours experienced by all users at each individual movement over the course of the weekday morning and weekday evening peak hours.

### Individual Person-Delay to Travel the Corridor

To better understand how delay will affect users by mode, the total cumulative average delay to travel the corridor experienced by each individual person was calculated and compared for people in vehicles versus people on buses. Table 3 summarizes the results of the total corridor-wide person-delay by mode expected to be experienced by the average person.

**Table 3 Individual Person-Delay to Travel the Corridor**

Mode	Direction	Weekday Morning Peak Hour			Weekday Evening Peak Hour		
		2020 Build	Concept	Change	2020 Build	Concept	Change
Transit Person-Delay (seconds) <sup>a</sup>	Inbound (EB)	205	55	-150	211	53	-158
	Outbound (WB)	368	77	-291	316	67	-249
Vehicle Person-Delay (seconds) <sup>b</sup>	Inbound (EB)	248	540	+292	198	423	+225
	Outbound (WB)	285	281	-4	312	360	+48

a Transit Person-Delay for movements along the proposed bus lanes (Washington Street and Route 9).  
 b Vehicle Person-Delay for through movements along Route 9.

As shown in Table 3, the average amount of delay expected to be experienced by a person on a bus traveling through the corridor will decrease by up to 291 seconds per directional trip with the installation of the bus lanes, while the average amount of delay expected to be experienced by a person in a vehicle traveling through the corridor will increase by up to 292 seconds. The greatest time saving for passengers on buses will be in the outbound (westbound)

direction while the greatest increase in delay for people in vehicles will be in the inbound (eastbound) direction. It's important to note that the time savings for bus passengers are also likely to translate to time savings along other sections of the route. So, while these calculations are specific to riders on the Route 66 or Route 65 bus along this segment of the route, there are also passengers along other segments of the routes that would benefit with travel time savings.

### Cumulative Person-Delay for Each Individual Movement

In addition to calculating the total person-delay for each individual person to travel the corridor, the cumulative person-delay at each movement was summed over the entire course of the weekday morning and weekday evening peak hours. Tables 4 and 5 show the total peak hour movement delay for people on transit (Table 4) versus in vehicles (Table 5) at each movement in the corridor with and without dedicated bus lanes. To calculate the comparative delays, the average delay experienced by all people (by mode) was summed.

**Table 4 Cumulative Transit Person-Delay (Hours)**

Intersection	Movement	Weekday Morning Peak Hour		Weekday Evening Peak Hour	
		2020 Build	Concept	2020 Build	Concept
1	Washington St SB L	11	6	4	2
	Washington St WB R	7	2	6	4
2	Washington St EB T	22	2	8	1
	Washington St WB T	6	1	8	2

	Washington St EB T	0	1	2	1
	Washington St WB T	10	2	14	2
	Brookline Ave SB R <sup>a</sup>	0	0	1	1

a Movement does not include bus lane.

**Table 5 Cumulative Vehicle Person-Delay (Hours)**

Intersection	Movement	Weekday Morning Peak Hour		Weekday Evening Peak Hour	
		2020 Build	Concept	2020 Build	Concept
1	Washington St SB L	9	18	8	16
	Washington St WB R	14	29	6	18
2	Washington St EB T	61	176	46	127
	Washington St WB T	37	14	29	39
3	Washington St EB L <sup>a</sup>	47	39	9	6
	Washington St EB T	2	20	13	27
	Washington St WB T	48	29	74	109
	Brookline Ave SB R <sup>a</sup>	10	2	3	4

a Movement does not include bus lane.

Table 4 shows that bus ridership delay decreased, in some cases substantially, for most movements. In comparison, Table 5 shows that most of the delays for people in vehicles are increased for a majority of movements. This is reflective of the number of vehicle lanes being cut in half while serving similar demands.

The analyses presented in Tables 4 and 5 both assume that the volumes on the corridor will be the same under the 2020 Design Condition as under the three alternatives. In reality, a portion of the volumes are likely to divert or change modes due to the increased delays caused by the reduced vehicle capacity on the corridor. A discussion of the potential reduced and diverted demand is provided later in this memorandum.

### Intersection Processing Analyses

Additional analyses have been conducted to understand the processing capacity of the corridor under the 2020 Design plan and under the three bus-lane alternatives. Specifically, analyses have been conducted to understand the number of cycles that will be needed to clear the 95<sup>th</sup> percentile queue and the overall recovery time needed after the peak periods to recover back to non-peak levels of operations and delay.

### Time Needed to Clear Queue

An analysis has been conducted to determine how long it will take a vehicle on Route 9 to clear the first traffic signal on the corridor when approaching the corridor when the queue is almost at its peak. This analysis is based on the 95<sup>th</sup> percentile queues presented in Table 2. The analyses have been completed for the Route 9 eastbound approach at the intersection of Washington Street / High Street and the Route 9 westbound approach at the intersection of Brookline Avenue, as these are the first traffic signals a driver will encounter in each direction. A summary of the number of cycles and maximum time needed to process the 95<sup>th</sup> percentile queues is presented in Table 6.

**Table 6 Number of Cycles and Time Needed to Clear Max Queue**

Condition	Time Period	Route 9 EB Approach (at Washington Street/High Street)			Route 9 WB Approach (at Brookline Avenue)		
		95 <sup>th</sup> Percentile Queue	# of Cycles Needed to Clear Queue	Time Needed to Clear Queue	95 <sup>th</sup> Percentile Queue	# of Cycles Needed to Clear Queue	Time Needed to Clear Queue
2020 Design	AM Peak Hour	914 ft	2 cycles	260 seconds	508 ft	1 cycle	130 seconds
	PM Peak Hour	504 ft	1 cycle	120 seconds	586 ft	2 cycles	240 seconds
Alt. 1	AM Peak Hour	1,875 ft	4 cycles	560 seconds	744 ft	2 cycles	280 seconds
	PM Peak Hour	1,149 ft	2 cycles	300 seconds	1,054 ft	2 cycles	300 seconds
Alt. 2/3	AM Peak Hour	1,698 ft	3 cycles	390 seconds	920 ft	3 cycles	390 seconds
	PM Peak Hour	951 ft	2 cycles	240 seconds	1,054 ft	3 cycles	360 seconds

Note: Alternative 1 includes modified signal timings and phasing over 2020 Design Conditions and Alternative 2/3.

As shown in Table 6, under the 2020 Design Condition the 95<sup>th</sup> percentile queue is expected to be processed in one or two traffic cycles for the first intersections approached on Route 9. Under the three Alternatives, the number of cycles needed at each intersection to process the queue increases to three or four cycles at some locations resulting in a total time needed to clear the queue of up to 560 seconds. It should be noted that these analyses are based on the green and yellow time for each approach and assumes that when the light turns green on the Route 9 approaches the queue will begin to be processed. The analyses do not take into account downstream queues and delays (for example in Boston at Huntington/South Huntington Avenue) which may restrict the processing capacity of each intersection.

### Recovery Time

The recovery time is the amount of time needed after the end of the peak period to process the additional vehicles that were not able to be processed during the peak period. Since the volumes during the peak hour may exceed to available capacity, additional time may be needed at the end of the peak period to process the additional vehicles that could not be processed during the peak period. The analyses have been completed for the Route 9 eastbound approach at the intersection of Washington Street / High Street and the Route 9 westbound approach at the intersection of Brookline Avenue, as these are the first traffic signals a driver will encounter in each direction. A summary of the recovery time is presented in Table 7.

**Table 7 Recovery Time**

Condition	Time Period	Route 9 EB Approach (at Wash. Street/High Street)	Route 9 WB Approach (at Brookline Avenue)
2020 Design	AM Peak Hour	n/a	n/a
	PM Peak Hour	n/a	n/a
Alt. 1	AM Peak Hour	90 minutes	n/a
	PM Peak Hour	50 minutes	n/a
Alt. 2/3	AM Peak Hour	90 minutes	n/a
	PM Peak Hour	50 minutes	n/a

Note: Recovery Time of n/a means that the volume to capacity ratio for the approach is under 1.00 and the volume approaching the intersection during the peak period should be processed during the peak period.

As shown in Table 7, under the 2020 Design Condition both approaches on Route 9 should be able to process the approaching volumes during the peak period and therefore additional recovery time is not expected to be required. Under the three alternatives, recovery time of 50-90 minutes will be needed on the Route 9 eastbound approach to account for the reduction in capacity from two general-purpose lanes to one general-purpose lanes. It should be noted that these analyses assume the non-peak volumes will be less than the available capacity and that the recovery time is able to start as soon as the peak period ends.

Similar to the person-delay analyses, the analyses presented in Tables 6 and 7 both assume that the volumes on the corridor will be the same under the 2020 Design Condition as under the three alternatives. In reality, a portion of the volumes may divert or change modes due to the increased delays caused by the reduced vehicle capacity on the corridor. A discussion of the possible reduced and diverted demand is provided in the following section.

### Reduced and Diverted Demand

The analysis above focuses on the implications of providing dedicated bus lanes within the study area while maintaining 2019 peak traffic volumes. With the incorporation of dedicated bus lanes and the elimination of travel lanes through the corridor, non-bus traffic is expected to incur increased delays. However, the MBTA has seen an increase in transit ridership and a decrease in traffic volume along corridors where dedicated bus facilities have been previously installed. Therefore, it is reasonable to assume some traffic diversion would be likely in Brookline as well. The above analyses reflect the worst-case delay/congestion conditions if no diversion or mode shift occurs. This section reflects on the worst case for diversion potential by assuming that the traffic operations expected once the Gateway East project is complete can be maintained with the addition of dedicated bus lanes. In order to maintain current traffic delays with reduced capacity, a mode shift from vehicle to bus and/or a diversion of traffic away from the Gateway East area are needed.

Provision of a dedicated bus lane, regardless of the concept chosen, has a large impact on Route 9 traffic flow. The amount of traffic flow through the area during the peak hours appears to be driven by operations at the intersection

of Route 9 at Pearl Street/Jupiter Street, specifically the eastbound movement. In order to maintain traffic operations as they are under current conditions, it was determined that 575 morning peak hour and 405 evening peak hour vehicles, representing about 30 percent of total traffic volume, would need to be removed or diverted from the network. This could occur in a number of ways, primarily: by switching travel mode, altering travel time, or by altering travel route. The MBTA has anecdotal data that suggests traffic volumes may reduce by up to 20 percent when dedicated bus lanes are established. The data suggest bus ridership in the same area increases by about five percent, with the rest of the displaced traffic finding an alternate route, which may be regional or local. In cases where these diversions are evident, there has not been registered complaints of increased traffic on adjacent streets. This suggests that while route choice is affected, a large portion of the diverted traffic may be classified as "cut-through" and be returning to the primary routes they originally diverted from.

In the case of the Gateway East study area, a 20 percent reduction in traffic volumes would not be sufficient to offset travel impacts associated with the implementation of dedicated bus lanes. An additional 190 morning peak hour trips and 135 evening peak hour trips would have to be diverted from the corridor to maintain existing operational levels of service. Local trips may have the option to divert an increased percentage to the adjacent bus routes or Green Line D-branch. Trips of a more sub-regional nature may divert to one of two adjacent neighborhood routes, depending on their ultimate origin or destination:

- › Northbound –Cypress Street to Aspinwall Avenue
- › Southbound – Cyprus Street to Walnut Street to Pond Avenue or to Jamaicaway

A review of broad-level Street Light data suggest that up to 30 percent of traffic on Route 9 in Gateway East is destined to the Longwood Medical Area (LMA). Based on this information, it is reasonable to assume that up to 30 percent of the traffic that may divert would choose a northbound bypass route. The street light data suggest that up to 60 percent of the traffic on Route 9 in Gateway East is destined to Jamaica Plain, the Tremont Street Corridor, and points east (including I-93). Trips that may divert from Route 9 to these destinations are likely to choose the southbound bypass route via Pond Avenue and the Jamaicaway. The remaining 10 percent are estimated to be destined to the Huntington Avenue Corridor, Copley Square, and downtown Boston. Portions of traffic with these destinations may divert to Walnut Street via Cyprus Street and rejoin the Route 9 corridor at Pond Street or Walnut Street.

It is noted that as of summer 2020, traffic volumes along Route 9 were reduced by about 40 percent compared to 2019 conditions. Under current conditions, the Gateway East area could maintain planned traffic operations without any diversions. It is difficult to pinpoint exactly how many vehicles may divert from the corridor as traffic volumes return to 2019 levels (or how quickly a return to these levels may occur) and which route they might choose. If dedicated bus lanes are implemented, the town should monitor traffic volumes on adjacent local roads and may have to consider additional mitigation along these routes to discourage travel as a way to bypass Route 9.

## Proposed Concepts – Traffic Design Issues/Implications

Beyond the calculation of potential benefits and impacts associated with the addition of dedicated bus lanes, the ongoing MassDOT construction project presents a number of challenges from a traffic design perspective. These challenges do not

invalidate the benefits of a dedicated bus facility for transit users. However, they will have to be addressed in some way as part of the bus lane implementation to maintain traffic safety in the study area.

- › **Brookline Avenue dual left-turns southbound to eastbound Route 9 (easterly project limits).** With the dedicated bus lane, only one receiving lane remains on Route 9 eastbound. This would require a change in the Brookline Avenue geometry to allow only one left-turn lane from Brookline Avenue to Route 9 EB. The queuing impacts of reducing the number of left-turn lanes are substantive and cannot be modeled accurately in synchro due to their anticipated length. We are highlighting the potential to drop exclusive use of a dedicated bus lane on Route 9 eastbound between Brookline Avenue to Pond Avenue (~200 feet). In this section, the bus lane could be striped with red dashed paint to denote shared use.
- › **Route 9 eastbound, west of High Street (westerly project limits).** This approach has two departure lanes through the intersection and is reduced to one receiving lane in front of the Fire Station due to adding bus lane (~175 feet). Geometrically, our recommendation is to reduce the approach to one through lane and one right-turn lane (to High Street). There is plenty of available distance on Route 9 to accommodate the increased queuing, although there is the potential for bottleneck issue where the lane drop occurs (where the impatient driver tries to go around the queue and cut in). This approach of Route 9 is under MassDOT jurisdiction and the town/MBTA would need to get state approval to drop the lane. An alternate solution to this would be to have a shared bus/vehicle lane along Route 9 in front of the firehouse.
- › **Route 9 eastbound at Pearl Street.** In conjunction with above, we reviewed maintain 2 lanes eastbound along Route 9 through Pearl Street, restricting eastbound left-turns from Route 9 to Pearl Street and converting the left-turn lane to a through lane. There are lane alignment concerns associated with this change, as traffic traveling in the left-most through lane would be forced to turn left onto Brookline Avenue. However, given the high left-turn volume at Brookline Avenue, this may be an acceptable compromise. Eastbound traffic destined to Pearl Street would also turn left onto Brookline Avenue and access Pearl Street at its intersection with Brookline Avenue. It is not possible to provide a U-turn for Route 9 eastbound traffic.
- › **High Street Northbound at Route 9.** The short block of High Street between Walnut Street and Route 9 (approximately 120 feet) currently provides two northbound through lanes to Washington Street and into Brookline Village. The westbound dedicated bus lane will eliminate a receiving lane for this traffic on Washington Street. In this case, it is suggested to allow for a shared use of the dedicated bus facility between Route 9 westbound and its terminus at Station Avenue. High Street south of Walnut Street experiences substantial queuing under current conditions and exacerbating conditions here would not likely be supportive by residents.
- › **Bus Blocking by excessive queuing at signals.** The inbound 95<sup>th</sup> percentile queue at Washington Street southbound at High Street increases from 294 feet to 817 in the morning and 261 feet to 788 feet in the evening. The outbound 95<sup>th</sup> percentile queue at Washington Street westbound at Brookline Avenue increases from 508 feet to 920 feet in the morning and 586 to 1054 feet in the evening. Without making the determination about whether the queue increase would be acceptable, queues would block access to the beginning of the eastbound bus lanes, which reduce their benefit. In the westbound direction, it is assumed the bus is already in a dedicated bus lane in Boston, the impact of the queue increase on the bus is eliminated.

Given the overall benefits, impacts, and challenges with installation of the dedicated bus lanes, and in lieu of the recent MassDOT construction project, which is now substantially complete, it appears that dedicated bus lanes can be installed in the westbound direction without extensive disruption or requirements for reconstruction. Provision of dedicated bus lanes in the eastbound direction, regardless of the concept, will likely require more substantive design changes, potential reconstruction of the separated bike lane, and further coordination with MassDOT to modify sections of state highway. A dedicated bus lane in the eastbound direction will take longer to implement due to these challenges. It is likely most beneficial to focus efforts on a westbound dedicated bus lane at this time and follow with eastbound changes in the future.

Subject: Gateway East Proposed Inbound Bus Lane

The MBTA/VBH proposal to provide two dedicated bus lanes, one eastbound one westbound, promises to provide improved public transit operations by enabling buses to transit the Gateway East Corridor in a faster time.

The Westbound bus lane is projected by VBH as having a small impact on general traffic and congestion, while the Eastbound lane potentially has a large impact on general traffic, as measured by doubling of the eastbound vehicle queue lengths key intersections, such as that at High St/Washington St:

VBH in its memo on Traffic Design Implications identifies five challenges for the Eastbound lane and suggest that a Westbound lane could be installed “without extensive disruption”, but an Eastbound lane requires “more substantive design”.

Consequently, this memo will focus on the Eastbound bus lane at the morning peak hour traffic, looking at the concerns for the potential of increased eastbound bus delays particularly incurred by buses trying to enter the bus lane, and, in this context, suggest a three-phase pilot approach.

First some background on the bus routes and proposed bus lane design.

Bus Routes Inbound Through Gateway East Corridor

There are three bus routes inbound (eastbound) transiting the Corridor:

- Route 60 goes down High Street, along Walnut crossing Rte 9 (Washington) at Pearl St
- Route 65 goes from Washington St (Village), merging onto Rte 9, proceeding turning left down Brookline Avenue
- Route 66 goes down Harvard St (Village) merging onto Rte 9, and proceeding along to Huntington Avenue

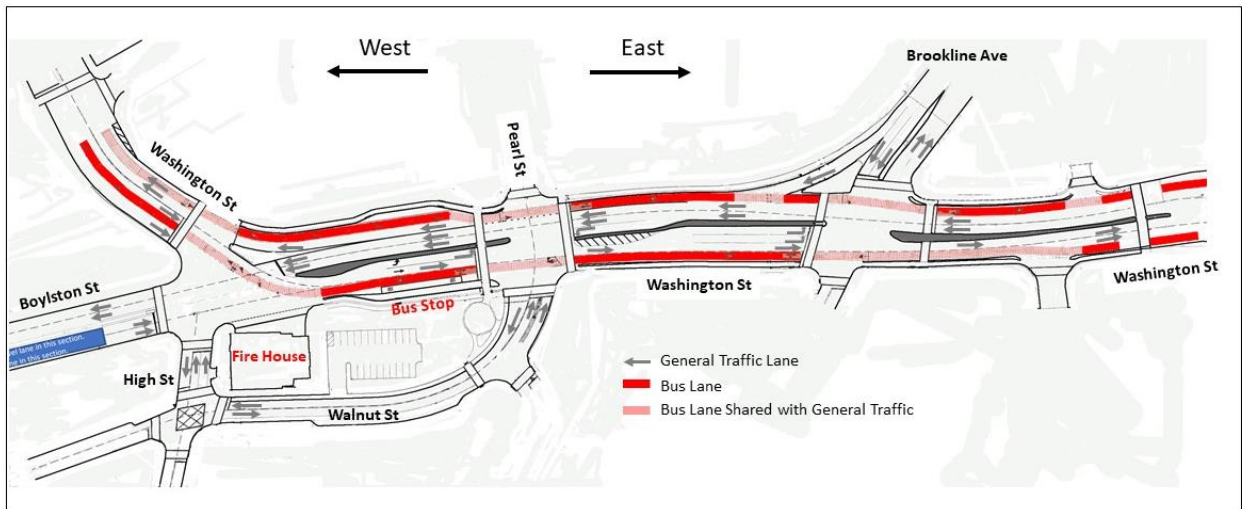

Bus Lane Schematic and Route Usage

The Bus Lane Schematic below (sourced from VBH), shows two bus lanes in red, one eastbound (High Street toward Brookline Ave) and one westbound.

The eastbound bus lane starts just after the Washington St/Station St. intersection on the approach to the High St intersection and has five separate segments linked by shared lane with general traffic. In the second segment here is a bus stop just beyond the Fire House on Washington street.

According to VBH, to provide for each bus lane, a general traffic through lane in each direction has been re-assigned to a dedicated or shared bus lane. Westbound, two through lanes remain for general traffic which would result in small delays. The Eastbound lane, on the other hand has been reduced to one through lane which results, according to VHB, in significant doubling of queue lengths, particularly for the High Street intersection.

In the bus lanes diagram below, the dark red indicates a dedicated bus lane and light red indicates shared lane with general traffic.

Route 60 (to Kenmore)

Route 60 would not use the proposed bus lane as it runs North-South across the Corridor, at Walnut and Pearl, but this route would be affected by increased delays on High St and at Walnut/Pearl intersections.

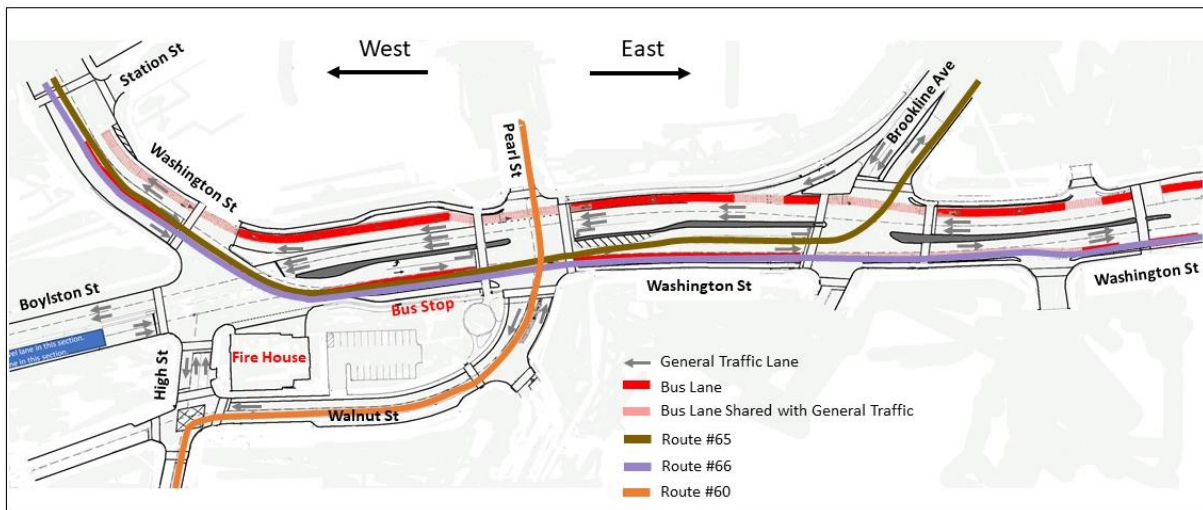

Route 65 (to Kenmore)

This route uses the bus lane only from Washington/Station street, where the lane starts, to the intersection with Route 9, to the bus stop (adjacent to the Fire House), then it leaves the bus lane at the Walnut/Pearl intersection, crosses the through traffic lane, to the dedicated left-turning lanes to proceed left down Brookline Avenue.

Route 66 (to Nubian Station)

This route uses the bus lane from Washington/Station street, where the lane starts to the continuation of the lane including a bus stop, adjacent to the Fire House, then proceeds east by the Brook House with a shared lane and rejoining a segment of the bus lane after Pond Street.

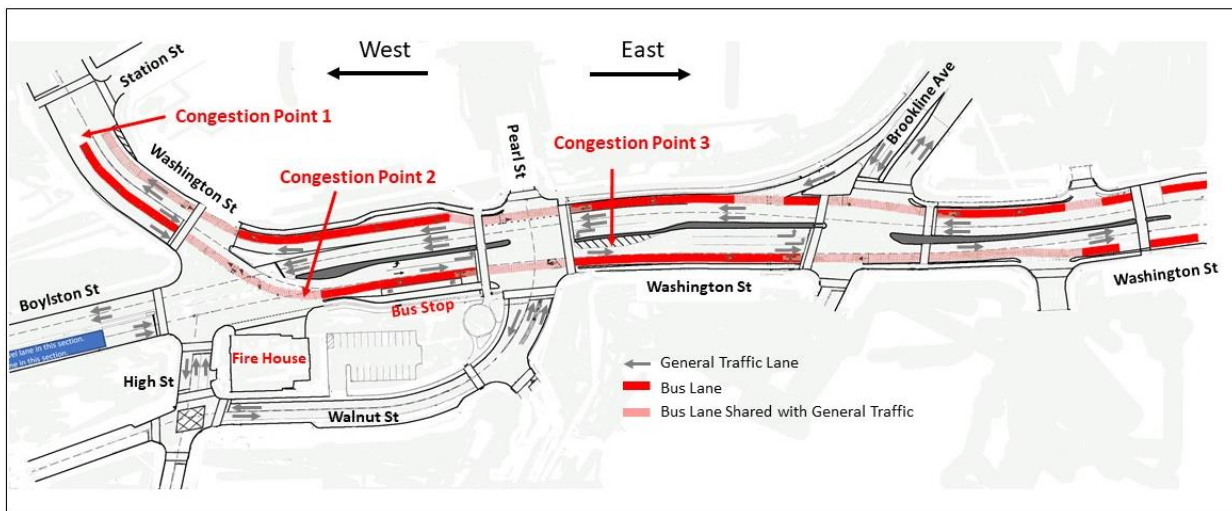

### Congestion Points

Congestion points are locations on the proposed Eastbound bus lane where there is likely traffic back-up congestion or vehicles re-positioning to avoid the bus lane, that would cause delays to buses trying to enter the bus lane.

Congestion Point 1 is at the start of the bus lane in the Village at Station St. This is where the current three lanes (one for right turning traffic, one for through/High St traffic and one through lane) are reduced to two lanes of general traffic, one on either side of the bus lane.

The consequences of this congestion point could be severe and affects both bus routes, #65 and #66. Not only does traffic likely back-up through the two signalized intersections, at Washington/Harvard and Washington/Station, and tie up traffic in the Village, but traffic lane changing, to avoid the bus lane, will add to congestion and consequent delays.

Congestion Point 2, just in front of the Fire House, is where two lanes of general traffic, from Washington St and Boylston St, merges into one, with the possibility of creating congestion at the intersection, blocking access to the bus lane.

Congestion Point 3 is just after the Pearl St intersection where general traffic is reduced to one lane for through traffic and two left turning lanes for traffic bound for Brookline Ave. The #65 route would be particularly impacted

by this congestion point, as its route at the Walnut/Pearl intersection takes it out of the bus lane, across the general traffic lane to position itself in the left turn only lanes to proceed down Brookline Ave.

The #65 and #66 bus routes are likely to incur delays at these three congestion points, increasing overall transit time across the Corridor. Consequently, any time savings made by these two bus routes on the eastbound bus lane will be offset by the delays in entering the bus lane.

### Traffic Lights

In the three signalized intersections in the Corridor, Traffic light signal delay, waiting for green, adds significantly to the corridor transit time. The #65 bus route is the most affected since it turns left at the Brookline Ave intersection with a short green light.

Very recently, during an on-site observation, one #65 bus took 51 seconds to get from Washington street/High Street intersection (close to start of proposed bus lane), to the left turn lane at the Brookline Ave intersection, and that included a passenger stop. Then, the bus waited for 103 seconds for a green left turn signal at that intersection, more than tripling its corridor transit time.

A Transit Signaling Priority (TSP) system, which enables buses to turn the signal to green as they approach the traffic light, can be installed in the new traffic signal controls and would provide significant reduction in Corridor transit times for buses.

### Conclusion

The eastbound bus lane is potentially quite problematic, not only for general traffic backing up significantly on Route 9 prior to the High Street intersection, but also for the buses at the intersections, where general traffic congestion can impede buses from entering the bus lane. It is quite possible that the effects of the congestion points described above, outweigh any travel time benefit for buses that the Eastbound lane might afford.

The eastbound side needs more work to evaluate the likelihood and effect of these congestion points and to maybe change roadway layout so that those effects can be mitigated. A study of the adjacent signalized intersections: Washington St/Station St; and Washington St/Harvard St needs to be done, to ascertain the full effect on the Village traffic from queuing at the High Street intersection and the potential for delay for buses trying to enter the bus lane at Station Street.

It seems clear that, if Transit Signal Priority (TSP) was implemented in the Corridor's signals, that this system would have a very beneficial effect on bus transit times, particularly the #65 bus, possibly having greater beneficial impact than that of the bus lane, particularly on light traffic days.

### Recommendation

In considering this information, I ask the Board to consider a three-phase pilot plan, with scope, timeframe and performance goals defined before pilot commencement. The three phases suggested are:

First, implement TSP on at least the three Gateway East intersections (more if possible) and measure the impact.

Second, that only the westbound bus lane is initially involved in a dedicated bus lane pilot. VHB points out that most of the projected benefits for transit riders from bus lanes are on the Westbound side and the delays or burden on general traffic are light. The effects on bus transit times and general traffic delays of both TSP and westbound lane pilot should be measured over this part of the pilot period against performance goals. In addition to traffic measurements, a ridership loading measure would be important to have as well to see if faster times are increasing ridership.

Third, during the initial pilot period, the engineers should study an improved Eastbound design to see whether the costs in potential time delays to buses outweigh the benefits of the bus lane travel or not, and if design mitigations can be provided to reduce or eliminate those burdens on general traffic.

It is quite possible that the first two steps of the pilot described here, are sufficient to provide all the necessary improvement in bus transit times and might well render it unnecessary to have an Eastbound pilot, particularly if bus transit times are not projected to be improved.

Timing of starting a pilot is important. The current Covid-affected traffic in the Corridor is light. In fact, buses on both bus routes were observed recently traveling across the Corridor under one minute, about as fast as a bus can go through the Corridor, with no general traffic delay at all. The start of the pilot should be set when traffic volumes are sufficient to be causing delays in bus corridor transit times, so that improvements can be measured.
